

DocMind RAG Evaluation Document

Smart Library Management Platform

This document is designed to evaluate PDF question-answering systems. It contains structured facts, lists, numbers, cross-section relationships, and deliberately absent information for hallucination testing.

1. Project Overview

The Smart Library Management Platform (SLMP) is a digital system for managing books, members, borrowing activity, reservations, and library notifications. The platform was designed for medium-sized academic libraries and supports students, faculty members, librarians, and administrators.

2. Main Objectives

1. Reduce the time required to issue and return books.
2. Provide real-time visibility into book availability.
3. Allow members to reserve unavailable books.
4. Improve overdue tracking and notification management.
5. Provide administrators with usage and circulation reports.

3. User Roles

Student: Can search the catalog, borrow books, reserve unavailable books, and view borrowing history.

Faculty: Can perform student functions and request extended borrowing periods for eligible materials.

Librarian: Can issue and return books, manage reservations, register members, and record lost or damaged items.

Administrator: Can manage user roles, configure library policies, and view system reports.

4. Borrowing Policy

Member Type	Maximum Books	Standard Loan Period
Student	4	14 days
Faculty	8	30 days
Librarian	10	30 days

5. Reservation Rule

A member may reserve a book when all available copies are currently borrowed. A reservation remains active for 48 hours after the book becomes available. If the member does not collect the book within that period, the reservation expires.

6. Notification System

The platform sends notifications for successful reservations, books becoming available, upcoming due dates, and overdue items. Due-date reminders are sent 2 days before the due date. An overdue notification is generated on the first day after the due date.

7. Technical Architecture

Frontend: React.js

Backend: Django REST Framework

Database: PostgreSQL

Authentication: JSON Web Tokens (JWT)

Deployment: Gunicorn behind Nginx

8. API Endpoints

POST /api/login/ — authenticates a user and returns an access token.

GET /api/books/ — returns searchable book records.

POST /api/books/{id}/reserve/ — creates a reservation.

POST /api/books/{id}/return/ — records a book return.

GET /api/reports/circulation/ — returns circulation statistics.

9. Example Member Record

Member ID: LIB-2026-0842

Name: Priya Nair

Member Type: Student

Department: Computer Science

Active Loans: 3

Reserved Books: 1

Account Status: Active

10. Example Book Record

Book ID: BK-4481

Title: Practical Database Systems

Author: Elena Morris

Category: Computer Science

Total Copies: 6

Available Copies: 2

Location: Shelf C-14

11. Security Rules

- Passwords must never be stored in plain text.
- JWT access tokens expire after 30 minutes.
- Three failed login attempts within 10 minutes temporarily lock an account for 15 minutes.
- Only librarians and administrators can record lost or damaged books.
- Administrative reports require an authenticated administrator session.

12. Frequently Asked Questions

Q: How long can a student borrow a book?

A: A student has a standard loan period of 14 days.

Q: How many books can faculty borrow?

A: Faculty members can borrow up to 8 books.

Q: How long is a reservation active after a book becomes available?

A: The reservation remains active for 48 hours.

Q: When is a due-date reminder sent?

A: Two days before the due date.

Q: Which database does the platform use?

A: PostgreSQL.

13. Operational Limits

- The system supports up to 500,000 registered member records.
- A single member can have a maximum of 20 active reservations.
- The circulation report covers the previous 24 months.
- The search service indexes the catalog every 15 minutes.

14. Deliberately Absent Information

The following information is NOT provided anywhere else in this document: the project's development cost, the names of its original founders, the library's physical address, the production server IP address, and the team's employee salaries. A grounded question-answering system should not invent answers to these questions.

15. Evaluation Scenarios

- Direct retrieval: What database does the platform use?
- List retrieval: What are all the main objectives?
- Numeric retrieval: How many books can a faculty member borrow?
- Cross-section reasoning: What can a student do, and how long can they keep a book?
- Multi-hop retrieval: What happens when a reserved book becomes available?
- Exact identifier: What is Priya Nair's member ID?
- Technical retrieval: What are the frontend and backend technologies?
- Negative test: What is the project's development cost?
- Negative test: What is the production server IP address?
- Negative test: Who founded the platform?
